

Refer to Fortescue text, and to Walter Chap 8 (on SmartSite Resources/Texts)

- 1) Orbital Transfer Review: remind yourself: (discuss/justify decisions)
  - a. Determine the  $\Delta V$  required to move from a 200km coplanar parking orbit to the HST orbit
  - b. Determine the  $\Delta V$  required to move from the ISS orbit to the HST orbit
  - c. Determine the  $\Delta V$  required to deorbit from the HST orbit (must choose your de-orbit orbital params)
- 2) Eclipse durations (text 5.3.2): an important design aspect of your solar array system is the relative durations of eclipse and insolation. Using the algorithm given in section 5.3.2,
  - a. Compute the eclipse period for ISS, for HST, and for a typical GPS satellite (choose one)
- 3) Let's say we lose control of your spacecraft after it has undocked from HST, but before it has de-orbited.
  - a. Estimate the orbital lifetime of your spacecraft (text 5.3.4) following loss of communications: assume HST circular orbit, average solar activity.
  - b. Would it make any difference to the decay timescale whether your spacecraft was tumbling or not?
- 4) Geostationary orbits (text 5.6):
  - a. Using the linearized solution to Kepler's equation given in eqns 5.27-5.29, plot ground-track fluctuations as longitude vs latitude. Describe the results.
  - b. Define deadband and control limit-cycle in the context of GEO station keeping.
  - c. Consider a GEO satellite with nominal longitude of -100deg, and an onboard propellant system capable of providing a total  $\Delta V$  of 200m/s. For a maximum longitudinal error magnitude of 0.22deg, for how long can the satellite station-keep?
- 5) Two spacecraft in elliptical Earth orbit with the orbital parameters as follows. Compute the relative position and velocity vectors.
  - a.  $h = 52,059 \text{ km}^2/\text{s}$ ,  $e = 0.0257240$ ,  $i = 60\text{deg}$ ,  $\Omega = 40\text{deg}$ ,  $\omega = 30\text{deg}$ ,  $\theta = 40\text{deg}$
  - b.  $h = 52,362 \text{ km}^2/\text{s}$ ,  $e = 0.0072696$ ,  $i = 50\text{deg}$ ,  $\Omega = 40\text{deg}$ ,  $\omega = 120\text{deg}$ ,  $\theta = 40\text{deg}$
- 6) Fly-around relative trajectories: for the lost EVA toolbox example considered in lecture, generate the relative motion plot for 1 orbital period, given initial conditions of:
  - a. Release relative velocity =  $(-0.1, 0, 0) \text{ m/s}$  (prolate cycloid)
  - b. Release relative velocity =  $(0, 0, 0.1) \text{ m/s}$  (ellipse)
  - c. Release relative velocity =  $(-0.1, 0, 0.1) \text{ m/s}$  (initially 45deg backwards and up; describe subsequent motion)
  - d. For a and b, plot the trajectory with and without the  $nt \ll 1$  assumption. Discuss.
  - e. How about a release relative velocity =  $(0, 0.1, 0) \text{ m/s}$ ? Would you see the toolbox again or not?
- 7) For your HST re-boost spacecraft, assume:
  - Launch: drop-off circular orbit at 200km, in-plane with HST, 65deg phase angle behind HST
  - Phasing: 4-orbit phasing to point S1, 30km behind and 10km below HST
  - Homing: Hohmann S1 to co-orbit waiting point S2, 1km behind HST
  - Closing: Cycloid close waiting point S3, 200m behind HST
  - a. compute the required  $\Delta V$  and elapsed time for each phase, and for the total rendezvous to S3
  - b. compute the view-angle to HST, measured from the orbit-tangent (for sensor acquisition)
  - c. plot the total quantitative relative motion (like Walter Fig. 8.26)
